Monkeypod, ʻōhai

Pithecellobium saman (Jacq.) Benth.

Legume family (Leguminosae)

Post-Cook introduction

Monkeypod is a familiar beautiful shade tree with large trunk and very broad arched crown of dense foliage. It has bipinnate leaves with many paired diamond-shaped leaflets that fold together at night and on cloudy days. The flower heads are a mass of threadlike stamens pink in outer half and white in inner half, and the flattened brown or blackish pods with sweetish pulp do not open. Mimosa subfamily (Mimosoideae).

A large introduced tree attaining 50–75 ft (15–23 m) in height, with relatively short trunk 2–4 ft (0.6–1.2 m) in diameter. Crown of long stout nearly horizontal branches broader than tall, becoming 80–100 ft (24–30 m) across. Bark gray, rough, thick, furrowed into long plates or corky ridges. Inner bark pink or light brown, bitter. Twigs stout greenish, minutely hairy. Nearly evergreen but almost leafless for a few weeks in spring after old leaves fall in February and March.

Leaves alternate, bipinnate, 10–16 inches (25–40 cm) long. The axis and 2–6 pairs of branches (pinnae) are green and finely hairy with swelling at base of each and gland dot on axis where branches join. Each branch bears 6–16 paired stalkless leaflets with gland dot between each pair. Branches toward apex are longer, with more leaflets. Leaflet blades ¼–1½ inches (2–4 cm) long and ⅜–⅝ inches (1–2 cm) broad, the outer largest, blunt to pointed at base, toothed on edges, the sides unequal, slightly thickened, upper surface shiny green and lower surface paler and finely hairy.

Flower clusters (heads or umbels) several near end of twig, each on green hairy stalk of 2½–4 inches (6–10 cm), about 2½ inches (6 cm) across and 1½ inches (4 cm) high, composed of many short-stalked narrow threadlike pinkish white flowers tinged with green. The narrow green calyx is tubular, about ⅛ inch (6 mm) long, five-toothed, finely hairy; the narrow green and pinkish tinged corolla ¼–⅜ inch (10–13 mm) long, tubular, five-lobed, and finely hairy; many stamens united in tube near base, with spreading very long threadlike filaments about ⅟8 inches (2.5–3 cm) long. Flowering from April to August in Hawaii.

Pods narrowly oblong, 4–8 inches (10–20 cm) long, ⅜–⅝ inch (15–19 mm) wide, and ⅛ inch (6 mm) thick, with raised border, straight or a little curved. Seeds several beanlike, oblong reddish brown, about ⅛ inch (8 mm) long.

The nutritious pods are relished by cattle, hogs, and goats. Some people chew the pods for the sweetish flavor like licorice. The tree is a honey plant. In a few countries this species has been employed as shade in

This information is from Agriculture Handbook no. 679 by Elbert L. Little Jr. and Roger G. Skolmen, published by the Forest Service, U.S. Dept. of Agriculture, in 1989. Its present format is that of a reprint version published by the College of Tropical Agriculture and Human Resources, University of Hawaii at Manoa, 2003.

Common Forest Trees of Hawaii (Native and Introduced)

plantations of coffee and cacao, but less so now than formerly. Because of their enormous growth the trees compete heavily for water and soil nutrients, inhibiting the shrubs planted beneath. The trees are easily propagated from seed and cuttings and grow rapidly. Cattle disseminate the seeds in pastures.

Monkeypod is a favorite shade tree of streets and parks in lowlands of Hawaii and is planted and naturalized in pastures. Because of its large size it is less suited for planting around homes. Sometimes trees become top-heavy and dangerous along highways and near houses. The many surface roots may also be objectionable. The trees are also messy, dropping sticky flower parts and pods on cars parked beneath. Perhaps the species is better suited to dry localities, where the size is smaller.

Special areas
Keahua, Foster

Champion
Height 104 ft (31.7 m), c.b.h. 30.8 ft (9.4 m), spread 140 ft (42.7 m). Kohala Forest Reserve, Muliwai, Hawaii (1968). A very large monkeypod in Moanalua Gardens, Oahu, has a crown that covers over ¾ acre (0.3 ha).

Range
Native from Mexico (Yucatan Peninsula) and Guatemala to Peru, Bolivia, and Brazil. Widely planted and naturalized elsewhere in continental tropical America from Mexico southward, throughout the West Indies and in Old World tropics. Common in Puerto Rico and the Virgin Islands and grown also in southern Florida.

Other common names
raintree; saman (Puerto Rico, Spanish); licorice, giant tibet (Virgin Islands); gumorni spanis (Yap)

Botanical synonyms
Albizia saman (Jacq.) Polhill & Raven, Samanea saman (Jacq.) Merr.

The generic name Pithecellobium, from Greek, Rape’s earring refers to the fancied resemblance of the coiled pods of some species such as ‘opiuma, Pithecellobium dulce. Somehow, the less suitable common name “monkeypod” has been applied in Hawaii to this species with its flat pods!

The Spanish word “saman” and the specific name origins of the English word raintree and its French equivalent have been given. Early travelers reported that the tree mysteriously produced “rain” at night and would not sleep underneath it. Others observed the grass to be greener beneath the trees during droughts. Probably, the “rain” was the excreta of cicada insects inhabiting the trees. The Spanish name dormilon refers also to the movements of the leaflets, which close in the dark, suggesting sleep at night. In droughty areas, grass is often green under the large spreading crowns while grass in the open is brown, simply because it is exposed to the sun. Insects defoliate many trees each spring, but trees recover leaves rapidly.

Earpod-tree (Enterolobium cyclocarpum (Jacq.) (Griseb.) is a similar giant deciduous tree introduced for shade and ornament in Hawaii, mainly in dry lowlands. This tree is recognized by (1) short stout trunk with gray bark and thin spreading crown broader than high; (2) alternate twice-pinnate leaves with numerous paired oblong leaflets ¾–½ inch (10–13 mm) long; (3) flowers in whitish balls about 1 inch (25 mm) across numerous threadlike white stamens; and (4) very distinctive blackish seed pod, flattened and curved in a circle 3½–4½ inches (9–11 cm) in diameter, slightly resembling an ear. Planted as a street tree in Hawaii, growing rapidly but large for use around homes. A very large tree is in Foster Botanic Garden, Honolulu. Under the Spanish names guanacaste and genicero, the wood is used elsewhere for construction, carpentry, interiors, furniture, and veneer. Native from Mexico south through Central America to northern South America and introduced as a shade tree in other tropical regions.
